What is the difference between HashMap and ConcurrentHashMap?

💎 **Final Interview-Level Answer (Remember This Structure)**

1 **Thread Safety**

- HashMap is not thread-safe.
- ConcurrentHashMap is thread-safe and designed for concurrent access.

2 **Locking Behavior**

- HashMap does not use locking.
- ConcurrentHashMap uses fine-grained locking (locks only specific bucket/node during write operations).

3 **Performance**

- HashMap is faster in single-threaded environments.
- ConcurrentHashMap performs better in multi-threaded environments due to partial locking.

4 **Null Handling**

- HashMap allows one null key and multiple null values.
- ConcurrentHashMap does not allow null keys or null values.

Why do you think ConcurrentHashMap does NOT allow null values?

In concurrent systems:

If get() returns null, the thread cannot differentiate between:

- Key absent
- Key present but value is null

And in multithreaded environments, this ambiguity can create logical bugs.

So to avoid confusion and race-related inconsistencies,

👉 ConcurrentHashMap completely disallows null keys and values.

🧠 **Mini Memory Trick**

HashMap → Flexible (allows null)

ConcurrentHashMap → Strict (no null, thread-safe)

What is the difference between synchronizedMap() and ConcurrentHashMap?

"Why would you prefer ConcurrentHashMap over synchronizedMap in a high-traffic backend system?"

So here's the core idea:

- synchronizedMap() → Locks the **entire map** for every operation (read & write)
- ConcurrentHashMap → Allows **parallel reads** and uses **fine-grained locking for writes**

- In high-traffic systems, `synchronizedMap` locks the entire map for every read and write operation. This creates a bottleneck because only one thread can access it at a time.
- In contrast, `ConcurrentHashMap` allows parallel reads and uses fine-grained locking for writes, locking only specific buckets instead of the whole map.
- This improves scalability and throughput in multi-threaded environments.

In modern Spring Boot applications (like your JD mentions APIs and high-performing systems), where would you typically use ConcurrentHashMap?

Ans: Rate limiting

When request comes:

1Fetch (counter + timestamp)

2f currentTime - timestamp > 1 minute

→ Reset counter = 1

→ Update timestamp

3Else

→ If counter < limit → increment counter

→ Else → reject request (429 Too Many Requests)

Why is ConcurrentHashMap useful here instead of HashMap?
ConcurrentHashMap ensures thread-safe updates to user request counters, preventing race conditions when multiple API requests are processed simultaneously.

If your system runs on multiple servers (horizontal scaling)...Will ConcurrentHashMap still work correctly for rate limiting?
So what happens to your rate limit accuracy?
If limit = 5 requests/minute
User sends:

- 3 requests → Server A
- 3 requests → Server B

Each server thinks user made only 3 requests.
👉 Total requests served = 6
👉 But limit was 5
So rate limit is broken ❌

ConcurrentHashMap works only for:

- Single instance applications
- Local memory storage

It does NOT work for:

- Distributed systems
- Microservices with multiple instances

If we use Redis for distributed rate limiting: Why is Redis better than database for this?
first reason:
Redis is faster because it stores data in memory (RAM), while traditional databases rely on disk storage.
A normal DB SELECT → UPDATE sequence is not atomic by default, so it can cause lost updates under high concurrency.
Why Redis for rate limiting instead of DB?
1 Speed – Redis runs in RAM, much faster than disk-based DB.
2 Atomic operations – Commands like INCR are atomic, preventing race conditions.
3 Built-in expiry (TTL) – We can set automatic expiration for keys, perfect for time-based rate limiting.
4 Designed for high concurrency – Better suited for high-traffic APIs.

How would you implement distributed rate limiting in a Spring Boot microservices architecture?
1 Clarify the requirement:

- Are we limiting per API key, user, or IP?
- Are limits per second, per minute, per hour?
- This helps choose the right approach.

2 Use a distributed store:

- Local in-memory counters (ConcurrentHashMap) won't work across multiple instances.
- Use Redis (or Memcached) because it's fast, supports atomic operations, and works across all service instances.

3 Implementation approaches:
a) Token Bucket / Leaky Bucket using Redis:

- Maintain a counter per user/key with expiry.
- Use Redis INCR with TTL to atomically count requests.
- If count > limit → reject request (429 Too Many Requests).

b) Lua script in Redis for atomicity:

- Ensures increment and limit check are single atomic operation, avoids race conditions.

c) Spring Boot integration:

- Use Spring AOP / Interceptor to wrap endpoints.
- Annotate methods with @RateLimit(user=..., limit=..., period=...).

- Interceptor checks Redis counter before proceeding.

d) Optional enhancements:

- Sliding window counters for smoother rate limiting.
- Distributed cache clusters for high availability.
- Fallback if Redis is down → deny all or allow limited traffic.

4 Bonus points:

- Mention API Gateway-level rate limiting (like Zuul, Spring Cloud Gateway, Nginx) to offload enforcement from microservices.
- Mention monitoring & metrics (Prometheus + Grafana) to track rate-limited requests.

✅ One-liner summary you can drop confidently:

"I'd implement distributed rate limiting using Redis counters with atomic operations, wrapped in a Spring Boot interceptor or gateway filter, optionally using sliding windows for smoother limits."

1. Java 8+ and Core Internals
    - Java 8 Streams: "Explain the difference between map() and flatMap(). When would you prefer a parallel stream, and what are its overheads?"
    - Memory Management: "Describe the transition from PermGen to Metaspace. How do you identify a memory leak in a production environment?"
    - Optional Class: "Why shouldn't you use Optional as a parameter in methods or as a field in a class?"
    - JVM Tuning: "What are the common JVM flags you've used for performance tuning? Explain the difference between G1GC and ZGC."
2. Multi-threading & Concurrency (Critical for SDE II)
    - Synchronization: "Difference between synchronized block and ReentrantLock. How do you implement a 'Fair Lock'?"
    - Executor Service: "If a fixed thread pool is saturated, what happens to the new tasks? How do you choose between LinkedBlockingQueue and ArrayBlockingQueue for a thread pool?"
    - Advanced Tools: "Explain how CountDownLatch differs from CyclicBarrier. Give a real-life project use case for either."
    - Thread Safety: "How does ConcurrentHashMap achieve thread safety without locking the entire map? (Internal working of Segmentation vs. CAS)."
3. Spring Boot & Microservices
    - Spring Internals: "How does @SpringBootApplication work under the hood? Explain the role of @EnableAutoConfiguration."
    - Transaction Management: "How does @Transactional behave if a method calls another @Transactional method within the same class? (Proxy-based AOP issues)."
    - Microservices Patterns: "Describe the Saga Pattern for distributed transactions. How do you handle a failure in the middle of a Saga?"
    - Resilience: "How do you implement a Circuit Breaker (using Resiliency4j) to prevent cascading failures? What are the 'Open', 'Closed', and 'Half-Open' states?"
4. System Design & Databases
    - High-Level Design (HLD): "Design a system like Zomato (specifically mentioned in the JD). How do you handle real-time tracking of drivers?"
    - Low-Level Design (LLD): "Design a Vending Machine using Design Patterns (State Pattern, Factory Pattern)."
    - Database Optimization: "What is the N+1 query problem in Hibernate, and how do you fix it using Join Fetch or EntityGraph?"
    - NoSQL vs SQL: "When would you choose Redis over a relational database? Explain the eviction policies in Redis."
    - Consistency: "Explain the CAP Theorem. In a distributed system like Amazon's cart, would you prioritize Availability or Consistency?"
5. API Security & DevOps (JD Specific)
    - Security (OWASP): "How do you prevent SQL Injection and XSS in a Spring Boot app? What is the difference between JWT and OAuth2?"
    - API Management: "How do you implement Rate Limiting at the Gateway level (Kong/Apigee)? What is a 'Leaky Bucket' vs. 'Token Bucket' algorithm?"
    - Cloud & Deployment: "Describe a Blue-Green deployment strategy. How do you ensure zero downtime during a database schema migration?"
    - Testing: "Explain your strategy for Integration Testing. How do you use Testcontainers to test database-dependent code?"
6. Behavioral (Ownership & Agile)
    - Agile/Scrum: "How do you handle 'Scope Creep' in the middle of a sprint?"
    - Ownership: "Tell me about a time you identified a performance bottleneck in production that no one else saw. How did you fix it?"
    - Conflict: "Describe a situation where you had a technical disagreement with a Senior Architect. How was it resolved?"
